MVC - The Model View Controller Paradigm

- The Model controls the data

- The View controls the display

- The Controller handles the logic and brains of the program

Example: In the Calculator class.

The Model is your dictionary which holds on to the data ie when you get an operation, you need to take some action

The View is how you display the result. It can be print() or with decimals etc.

The Controller is the brains. It decides the logic. If the data recieved is "+" then lets add the numbers, else lets do something else.
